Chapter 2 Introduction

RAČUNARSKE MREŽE III- GODINA

Computer Networking: A Top Down Approach , 4th edition. Jim Kurose, Keith Ross Addison-Wesley, July 2007.

prof. dr Zlatko Langović

Chapter 2: Application layer

- 2.1 Principles of network applications
- 2.2 Web and HTTP
- **2.3 FTP**
- 2.4 Electronic Mail
 SMTP, POP3, IMAP
- **2.5 DNS**

- **2.6** P2P applications
- 2.7 Socket programming with TCP
- 2.8 Socket programming with UDP

Chapter 2: Application Layer

<u>Our goals:</u>

- conceptual, implementation aspects of network application protocols
 - transport-layer
 service models
 - client-server
 paradigm
 - peer-to-peer paradigm

learn about protocols by examining popular application-level protocols

- HTTP
- ✤ FTP
- SMTP / POP3 / IMAP
- DNS
- programming network applications
 - socket API

Some network apps

- 🗖 e-mail
- 🗖 web
- instant messaging
- 🗖 remote login
- P2P file sharing
- multi-user network games
- streaming stored video clips

- □ voice over IP
- real-time video conferencing
- □ grid computing

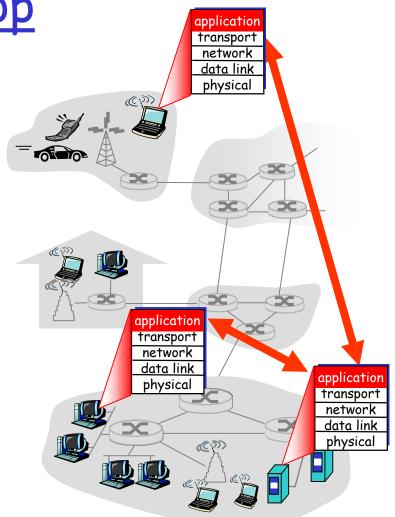

Creating a network app

write programs that

- run on (different) end systems
- communicate over network
- e.g., web server software communicates with browser software

No need to write software for network-core devices

- Network-core devices do not run user applications
- applications on end systems allows for rapid app development, propagation

Chapter 2: Application layer

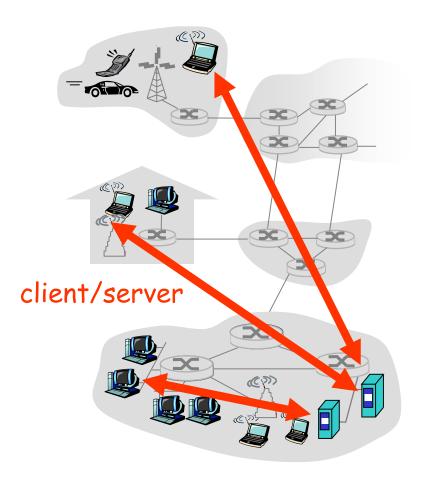

- 2.1 Principles of network applications
- 2.2 Web and HTTP
- **2.3 FTP**
- 2.4 Electronic Mail
 SMTP, POP3, IMAP
 2.5 DNS

- 2.6 P2P applications
- 2.7 Socket programming with TCP
- 2.8 Socket programming with UDP
- 2.9 Building a Web server

Application architectures

- Client-server
- Peer-to-peer (P2P)
- Hybrid of client-server and P2P

<u>Client-server architecture</u>

server:

- always-on host
- * permanent IP address
- server farms for scaling

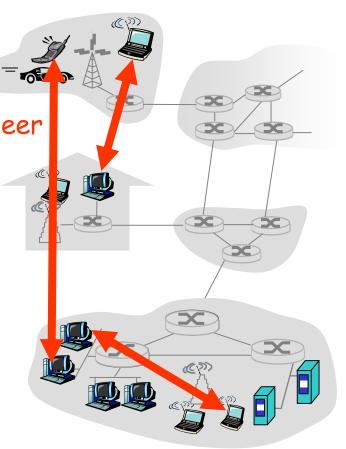

clients:

- communicate with server
- may be intermittently connected
- may have dynamic IP addresses
- do not communicate directly with each other

Pure P2P architecture

- □ *no* always-on server
- arbitrary end systems directly communicate
- peers are intermittently connected and change IP addresses

Highly scalable but difficult to manage

Hybrid of client-server and P2P

Skype

- voice-over-IP P2P application
- centralized server: finding address of remote party:
- client-client connection: direct (not through server)

Instant messaging

- * chatting between two users is P2P
- centralized service: client presence detection/location
 - user registers its IP address with central server when it comes online
 - user contacts central server to find IP addresses of buddies

Processes communicating

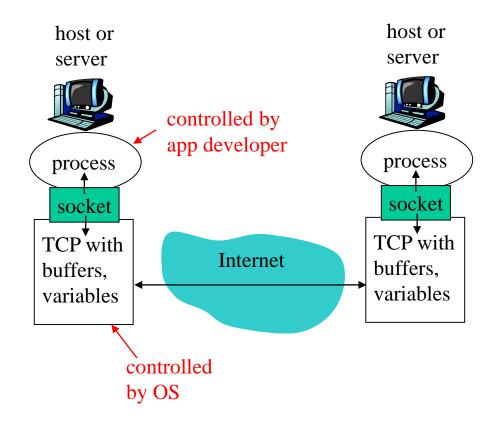

- Process: program running within a host.
- within same host, two processes communicate using inter-process communication (defined by OS).
- processes in different hosts communicate by exchanging messages

Client process: process that initiates communication Server process: process that waits to be contacted

Note: applications with P2P architectures have client processes & server processes

<u>Sockets</u>

- process sends/receives messages to/from its socket
- socket analogous to door
 - sending process shoves message out door
 - sending process relies on transport infrastructure on other side of door which brings message to socket at receiving process

API: (1) choice of transport protocol; (2) ability to fix a few parameters (lots more on this later)

Addressing processes

- to receive messages, process must have identifier
- host device has unique 32-bit IP address
- does IP address of host suffice for identifying the process?

Addressing processes

- to receive messages, process must have identifier
- host device has unique 32-bit IP address
- Q: does IP address of host on which process runs suffice for identifying the process?
 - A: No, many processes can be running on same host

identifier includes both IP address and port numbers associated with process on host.

- Example port numbers:
 - HTTP server: 80
 - Mail server: 25
- to send HTTP message to gaia.cs.umass.edu web server:
 - ✤ IP address: 128.119.245.12
 - Port number: 80
- □ more shortly...

App-layer protocol defines

- Types of messages exchanged,
 - e.g., request, response
- Message syntax:
 - what fields in messages & how fields are delineated
- Message semantics
 - meaning of information in fields
- Rules for when and how processes send & respond to messages

Public-domain protocols:
defined in RFCs
allows for interoperability
e.g., HTTP, SMTP
Proprietary protocols:
e.g., Skype

What transport service does an app need?

Data loss

- some apps (e.g., audio) can tolerate some loss
- other apps (e.g., file transfer, telnet) require 100% reliable data transfer

Timing

some apps (e.g., Internet telephony, interactive games) require low delay to be "effective"

Throughput

- some apps (e.g., multimedia) require minimum amount of throughput to be "effective"
- other apps ("elastic apps") make use of whatever throughput they get

Security

Encryption, data integrity, ...

Transport service requirements of common apps

Ap	Application Data loss		Throughput	Time Sensitive	
file	tranafar			no	
	e transfer	no loss	elastic		
	e-mail	no loss	elastic	no	
Web do	ocuments	no loss	elastic	no	
real-time au	dio/video	loss-tolerant	audio: 5kbps-1Mbps	yes, 100's msec	
			video:10kbps-5Mbps		
stored au	dio/video	loss-tolerant	same as above	yes, few secs	
	e games	loss-tolerant	few kbps up	yes, 100's msec	
instant m	essaging	no loss	elastic	yes and no	

Internet transport protocols services

TCP service:

- connection-oriented: setup required between client and server processes
- reliable transport between sending and receiving process
- flow control: sender won't overwhelm receiver
- congestion control: throttle sender when network overloaded
- does not provide: timing, minimum throughput guarantees, security

<u>UDP service:</u>

- unreliable data transfer between sending and receiving process
- does not provide: connection setup, reliability, flow control, congestion control, timing, throughput guarantee, or security
- Q: why bother? Why is there a UDP?

Internet apps: application, transport protocols

Applicati	on	Application layer protocol	Underlying transport protocol
e-m	nail	SMTP [RFC 2821]	ТСР
remote terminal acce	ess	Telnet [RFC 854]	TCP
We	eb	HTTP [RFC 2616]	ТСР
file trans	fer	FTP [RFC 959]	TCP
streaming multime	dia	HTTP (eg Youtube),	TCP or UDP
		RTP [RFC 1889]	
Internet telepho	ony	SIP, RTP, proprietary	
	-	(e.g., Skype)	typically UDP

Chapter 2: Application layer

- 2.1 Principles of network applications

 app architectures
 app requirements

 2.2 Web and HTTP
 2.4 Electronic Mail
 - SMTP, POP3, IMAP
- □ 2.5 DNS

- **2.6** P2P applications
- 2.7 Socket programming with TCP
- 2.8 Socket programming with UDP

Web and HTTP

First some jargon

- Web page consists of objects
- Object can be HTML file, JPEG image, Java applet, audio file,...
- Web page consists of base HTML-file which includes several referenced objects
- Each object is addressable by a URL
- **Example URL:**

```
www.someschool.edu/someDept/pic.gif
```

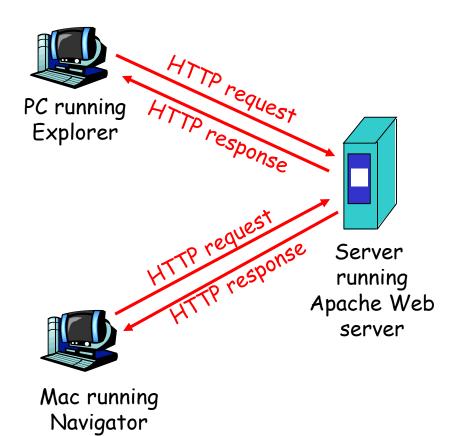

host name

path name

HTTP overview

HTTP: hypertext transfer protocol

- Web's application layer protocol
- client/server model
 - *client:* browser that requests, receives, "displays" Web objects
 - server: Web server sends objects in response to requests

HTTP overview (continued)

Uses TCP:

- client initiates TCP connection (creates socket) to server, port 80
- server accepts TCP connection from client
- HTTP messages (applicationlayer protocol messages) exchanged between browser (HTTP client) and Web server (HTTP server)
- TCP connection closed

HTTP is "stateless"

- server maintains no information about past client requests
- Protocols that maintain "state" are complex!
- past history (state) must be maintained
- if server/client crashes, their views of "state" may be inconsistent, must be reconciled

HTTP connections

Nonpersistent HTTP

At most one object is sent over a TCP connection.

Persistent HTTP

Multiple objects can be sent over single TCP connection between client and server.

Nonpersistent HTTP

Suppose user enters URL

www.someSchool.edu/someDepartment/home.index

(contains text, references to 10 jpeg images)

1a. HTTP client initiates TCP connection to HTTP server (process) at www.someSchool.edu on port 80

2. HTTP client sends HTTP request message (containing URL) into TCP connection socket. Message indicates that client wants object someDepartment/home.index

time

 1b. HTTP server at host
 www.someSchool.edu waiting for TCP connection at port 80. "accepts" connection, notifying client

3. HTTP server receives request message, forms *response message* containing requested object, and sends message into its socket

Nonpersistent HTTP (cont.)

4. HTTP server closes TCP connection.

5. HTTP client receives response message containing html file, displays html. Parsing html file, finds 10 referenced jpeg objects

time

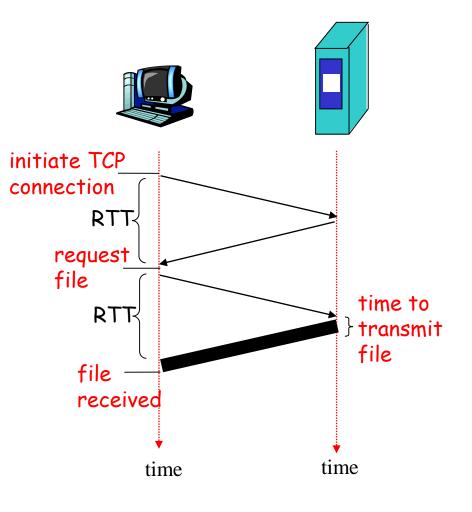

6. Steps 1-5 repeated for each of 10 jpeg objects

Non-Persistent HTTP: Response time

Definition of RTT: time for a small packet to travel from client to server and back.

Response time:

- one RTT to initiate TCP connection
- one RTT for HTTP request and first few bytes of HTTP response to return
- file transmission time
- total = 2RTT+transmit time

Persistent HTTP

Nonpersistent HTTP issues:

- requires 2 RTTs per object
- OS overhead for each TCP connection
- browsers often open parallel
 TCP connections to fetch
 referenced objects

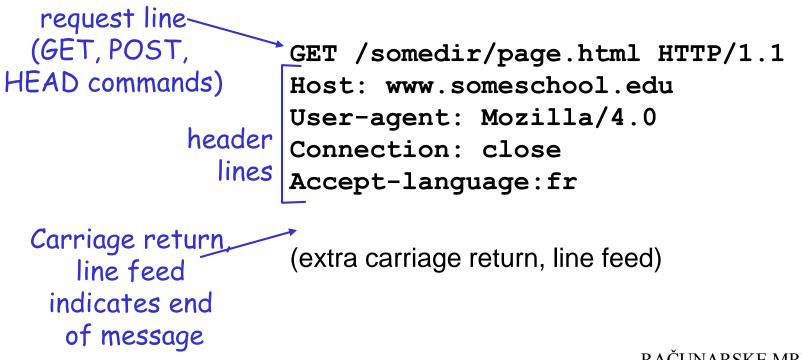

Persistent HTTP

- server leaves connection open after sending response
- subsequent HTTP messages between same client/server sent over open connection
- client sends requests as soon as it encounters a referenced object
- as little as one RTT for all the referenced objects

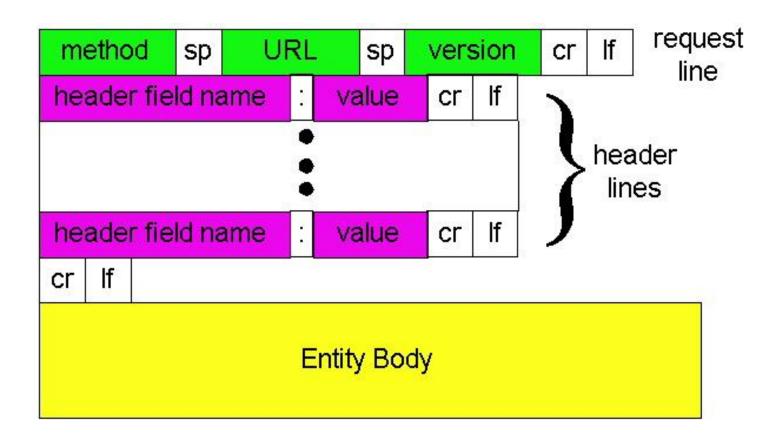

<u>HTTP request message</u>

two types of HTTP messages: *request*, *response* HTTP request message:

ASCII (human-readable format)

HTTP request message: general format

Uploading form input

Post method:

- Web page often includes form input
- Input is uploaded to server in entity body

URL method:

- Uses GET method
- Input is uploaded in URL field of request line:

www.somesite.com/animalsearch?monkeys&banana

Method types

- <u>HTTP/1.0</u>
- 🗆 GET
- D POST
- HEAD
 - asks server to leave requested object out of response

HTTP/1.1

- GET, POST, HEAD
- - uploads file in entity body to path specified in URL field
- DELETE
 - deletes file specified in the URL field

HTTP response message

status line (protocol <u>status code</u> status phrase)

> header lines

HTTP/1.1 200 OK Connection close Date: Thu, 06 Aug 1998 12:00:15 GMT Server: Apache/1.3.0 (Unix) Last-Modified: Mon, 22 Jun 1998 Content-Length: 6821 Content-Type: text/html

data, e.g., – requested HTML file

data data data data ...

HTTP response status codes

In first line in server->client response message. A few sample codes:

200 OK

- request succeeded, requested object later in this message
- 301 Moved Permanently
 - requested object moved, new location specified later in this message (Location:)
- 400 Bad Request
 - request message not understood by server
- 404 Not Found
 - requested document not found on this server
- 505 HTTP Version Not Supported

Trying out HTTP (client side) for yourself

1. Telnet to your favorite Web server:

telnet cis.poly.edu 80Opens TCP connection to port 80
(default HTTP server port) at cis.poly.edu.
Anything typed in sent
to port 80 at cis.poly.edu

2. Type in a GET HTTP request:

GET /~ross/ HTTP/1.1 Host: cis.poly.edu By typing this in (hit carriage return twice), you send this minimal (but complete) GET request to HTTP server

3. Look at response message sent by HTTP server!

<u>User-server state: cookies</u>

Many major Web sites use cookies

Four components:

- 1) cookie header line of HTTP *response* message
- 2) cookie header line in HTTP *request* message
- 3) cookie file kept on user's host, managed by user's browser
- 4) back-end database at Web site

<u>Example:</u>

- Susan always access Internet always from PC
- visits specific ecommerce site for first time
- when initial HTTP requests arrives at site, site creates:
 - onique ID
 - entry in backend database for ID

<u>Cookies: keeping "state" (cont.)</u> client server ebay 8734 usual http request msg <u>Amazon server</u> creates ID cookie file usual http response Set-cookie: 1678 1678 for user create entr ebay 8734 amazon 1678 usual http request msg access cookiecookie: 1678 specific backend usual http response msg one week later: action database access ebay 8734 usual http request msg cookieamazon 1678 cookie: 1678 spectific usual http response msg action

Cookies (continued)

What cookies can bring:

- authorization
- shopping carts
- recommendations
- user session state (Web e-mail)

How to keep "state":

- protocol endpoints: maintain state at sender/receiver over multiple transactions
- cookies: http messages carry state

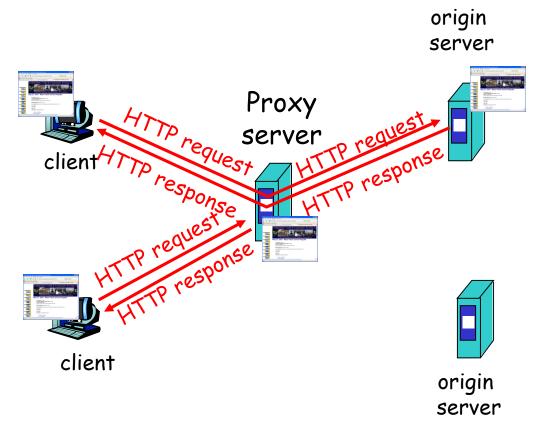

<u>Cookies and privacy:</u>

- cookies permit sites to learn a lot about you
- you may supply name and e-mail to sites

Web caches (proxy server)

Goal: satisfy client request without involving origin server

- user sets browser: Web accesses via cache
- browser sends all HTTP requests to cache
 - object in cache: cache
 returns object
 - else cache requests
 object from origin
 server, then returns
 object to client

More about Web caching

- cache acts as both client and server
- typically cache is installed by ISP (university, company, residential ISP)

Why Web caching?

- reduce response time for client request
- reduce traffic on an institution's access link.
- Internet dense with caches: enables "poor" content providers to effectively deliver content (but so does P2P file sharing)

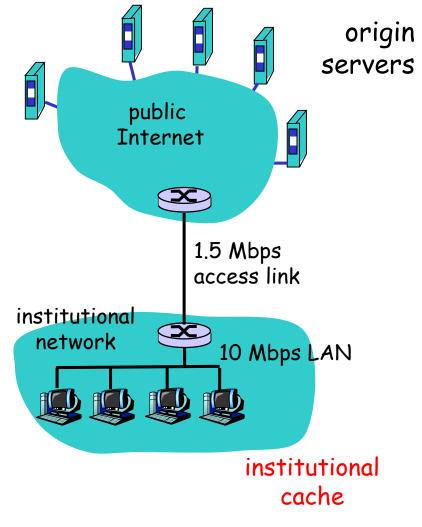

Caching example

Assumptions

- average object size = 100,000 bits
- avg. request rate from institution's browsers to origin servers = 15/sec
- delay from institutional router
 to any origin server and back
 to router = 2 sec

<u>Consequences</u>

- utilization on LAN = 15%
- utilization on access link = 100%
- total delay = Internet delay + access delay + LAN delay
- = 2 sec + minutes + milliseconds

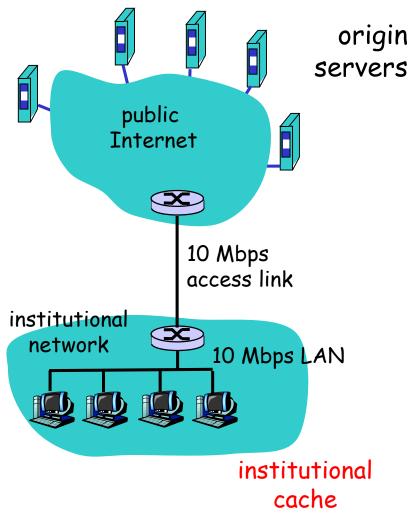

Caching example (cont)

possible solution

increase bandwidth of access link to, say, 10 Mbps

<u>consequence</u>

- utilization on LAN = 15%
- utilization on access link = 15%
- Total delay = Internet delay + access delay + LAN delay
 - = 2 sec + msecs + msecs
- often a costly upgrade

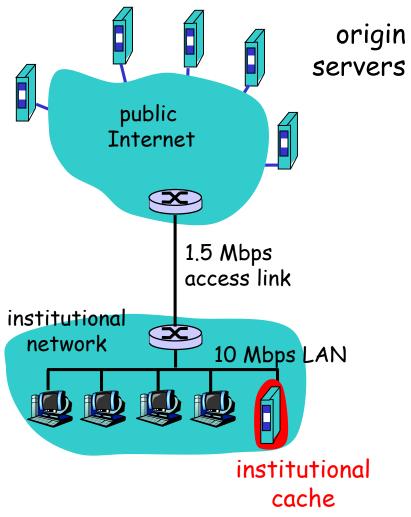

Caching example (cont)

- <u>possible solution: install</u> <u>cache</u>
- suppose hit rate is 0.4

<u>consequence</u>

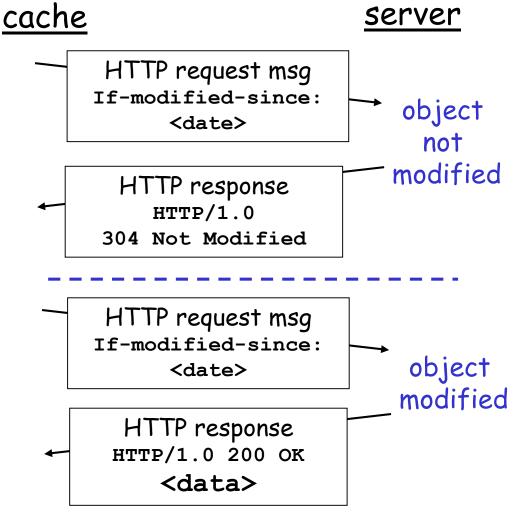

- 40% requests will be satisfied almost immediately
- 60% requests satisfied by origin server
- utilization of access link reduced to 60%, resulting in negligible delays (say 10 msec)
- total avg delay = Internet delay + access delay + LAN delay = .6*(2.01) secs + .4*milliseconds < 1.4 secs</p>

Conditional GET

- Goal: don't send object if cache has up-to-date cached version
- cache: specify date of cached copy in HTTP request If-modified-since: <date>
- server: response contains no object if cached copy is upto-date:

```
HTTP/1.0 304 Not
Modified
```

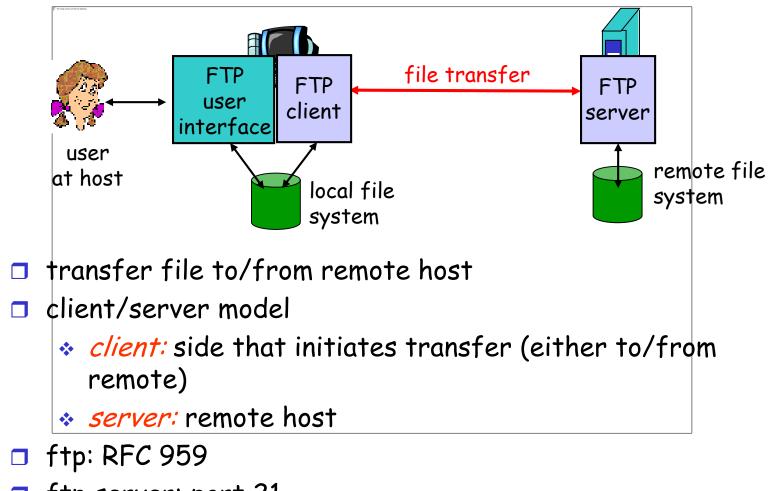

Chapter 2: Application layer

- 2.1 Principles of network applications
- 2.2 Web and HTTP
- □ 2.3 FTP
- 2.4 Electronic Mail
 SMTP, POP3, IMAP
 2.5 DNS

- **2.6** P2P applications
- 2.7 Socket programming with TCP
- 2.8 Socket programming with UDP
- 2.9 Building a Web server

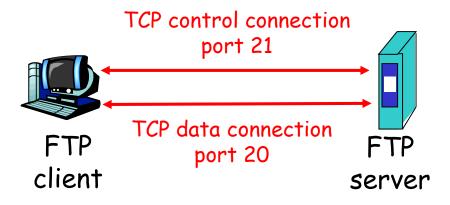

FTP: the file transfer protocol

□ ftp server: port 21

FTP: separate control, data connections

- FTP client contacts FTP server at port 21, TCP is transport protocol
- client authorized over control connection
- client browses remote directory by sending commands over control connection.
- when server receives file transfer command, server opens 2nd TCP connection (for file) to client
- after transferring one file, server closes data connection.

- server opens another TCP data connection to transfer another file.
- control connection: "out of band"
- FTP server maintains "state": current directory, earlier authentication

FTP commands, responses

Sample commands:

- sent as ASCII text over control channel
- 🗖 USER username
- 🗖 PASS password
- LIST return list of file in current directory
- RETR filename retrieves (gets) file
- STOR filename stores (puts) file onto remote host

Sample return codes

- status code and phrase (as in HTTP)
- 331 Username OK, password required
- 125 data connection already open; transfer starting
- 425 Can't open data connection
- 452 Error writing
 file

Chapter 2: Application layer

- 2.1 Principles of network applications
- 2.2 Web and HTTP
- **2.3 FTP**
- 2.4 Electronic Mail
 SMTP, POP3, IMAP
- **2.5 DNS**

- **2.6** P2P applications
- 2.7 Socket programming with TCP
- 2.8 Socket programming with UDP

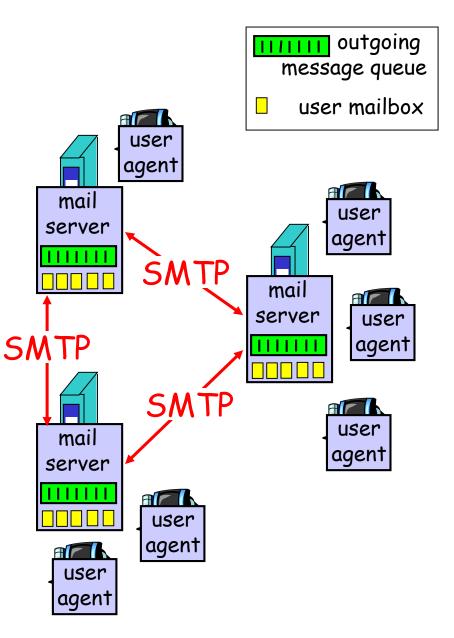

Electronic Mail

Three major components:

- 🗖 user agents
- mail servers
- simple mail transfer protocol: SMTP

<u>User Agent</u>

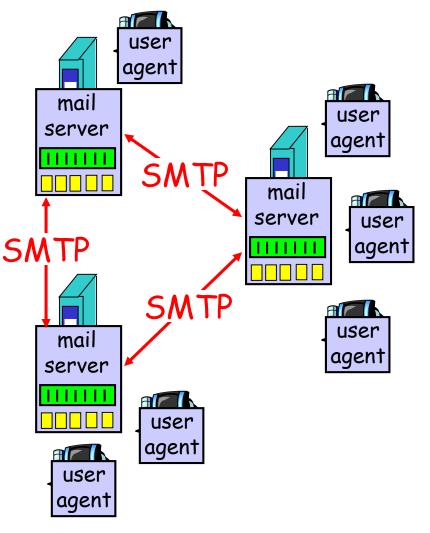

- a.k.a. "mail reader"
- composing, editing, reading mail messages
- e.g., Eudora, Outlook, elm, Mozilla Thunderbird
- outgoing, incoming messages stored on server

Electronic Mail: mail servers

Mail Servers

- mailbox contains incoming messages for user
- message queue of outgoing (to be sent) mail messages
- SMTP protocol between mail servers to send email messages
 - client: sending mail server
 - "server": receiving mail server

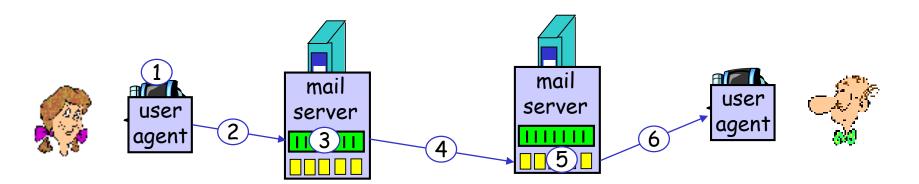

Electronic Mail: SMTP [RFC 2821]

- uses TCP to reliably transfer email message from client to server, port 25
- direct transfer: sending server to receiving server
- three phases of transfer
 - handshaking (greeting)
 - * transfer of messages
 - closure
- command/response interaction
 - commands: ASCII text
 - response: status code and phrase
- messages must be in 7-bit ASCII

Scenario: Alice sends message to Bob

- 1) Alice uses UA to compose message and "to" bob@someschool.edu
- 2) Alice's UA sends message to her mail server; message placed in message queue
- 3) Client side of SMTP opens TCP connection with Bob's mail server

- 4) SMTP client sends Alice's message over the TCP connection
- 5) Bob's mail server places the message in Bob's mailbox
- 6) Bob invokes his user agent to read message

Sample SMTP interaction

- S: 220 hamburger.edu
- C: HELO crepes.fr
- S: 250 Hello crepes.fr, pleased to meet you
- C: MAIL FROM: <alice@crepes.fr>
- S: 250 alice@crepes.fr... Sender ok
- C: RCPT TO: <bob@hamburger.edu>
- S: 250 bob@hamburger.edu ... Recipient ok
- C: DATA
- S: 354 Enter mail, end with "." on a line by itself
- C: Do you like ketchup?
- C: How about pickles?
- C: .
- S: 250 Message accepted for delivery
- C: QUIT
- S: 221 hamburger.edu closing connection

Try SMTP interaction for yourself:

- telnet servername 25
- □ see 220 reply from server
- enter HELO, MAIL FROM, RCPT TO, DATA, QUIT commands
- above lets you send email without using email client (reader)

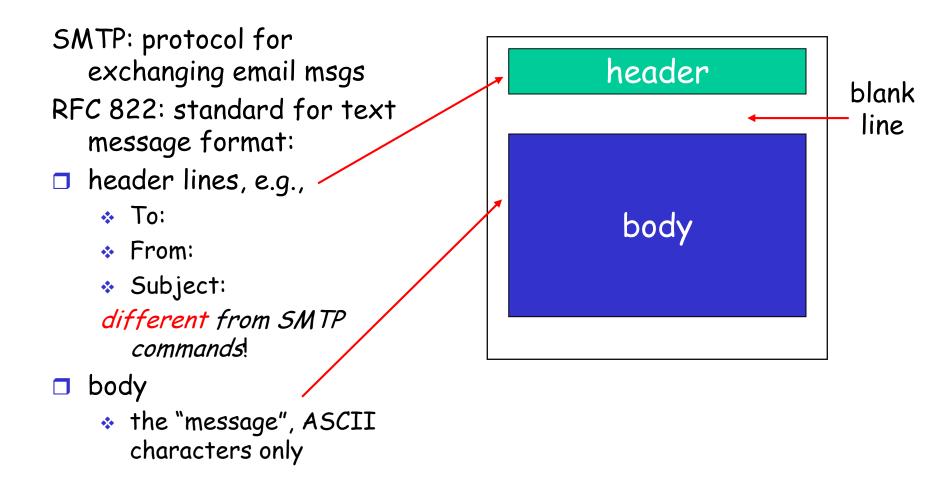

SMTP: final words

- SMTP uses persistent connections
- SMTP requires message (header & body) to be in 7bit ASCII
- SMTP server uses CRLF.CRLF to determine end of message

Comparison with HTTP:

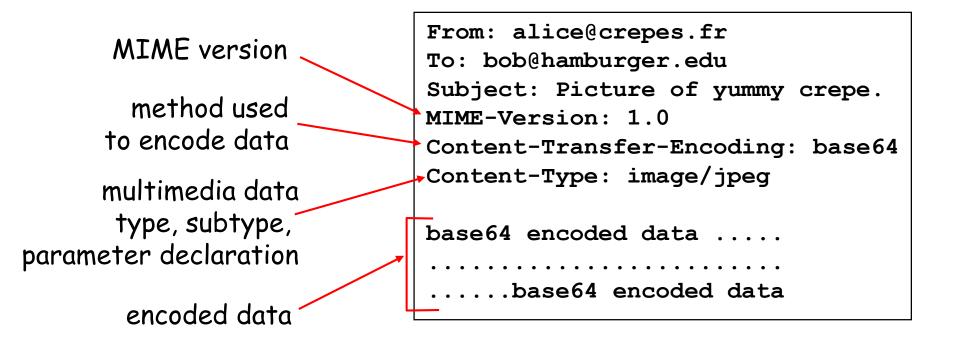

- □ HTTP: pull
- □ SMTP: push
- both have ASCII command/response interaction, status codes
- HTTP: each object encapsulated in its own response msg
- SMTP: multiple objects sent in multipart msg

<u>Mail message format</u>

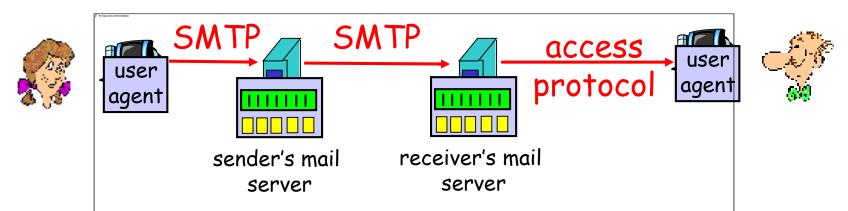

Message format: multimedia extensions

- **MIME:** multimedia mail extension, RFC 2045, 2056
- additional lines in msg header declare MIME content type

Mail access protocols

- □ SMTP: delivery/storage to receiver's server
- □ Mail access protocol: retrieval from server
 - POP: Post Office Protocol [RFC 1939]
 - authorization (agent <-->server) and download
 - IMAP: Internet Mail Access Protocol [RFC 1730]
 - more features (more complex)
 - manipulation of stored msgs on server
 - HTTP: gmail, Hotmail, Yahoo! Mail, etc.

POP3 protocol	
	S: +OK POP3 server ready
.	C: user bob
authorization phase	S: +OK
client commands:	C: pass hungry
	S: +OK user successfully logged on
* user: declare username	C: list
pass: password	S: 1 498
server responses	S: 2 912
↔ +OK	S: .
	C: retr 1
✤ -ERR	S: <message 1="" contents=""></message>
transaction phase, client:	S: .
•	C: dele 1
🗖 list: list message numbers	C: retr 2
retr: retrieve message by	S: <message 1="" contents=""></message>
number	S: .
🗖 dele: delete	C: dele 2
	C: quit
🗖 quit	S: +OK POP3 server signing off

POP3 (more) and IMAP

More about POP3

- Previous example uses "download and delete" mode.
- Bob cannot re-read email if he changes client
- Download-and-keep": copies of messages on different clients
- POP3 is stateless across sessions

IMAP

- Keep all messages in one place: the server
- Allows user to organize messages in folders
- IMAP keeps user state across sessions:
 - names of folders and mappings between message IDs and folder name

Chapter 2: Application layer

- 2.1 Principles of network applications
- 2.2 Web and HTTP
- **2.3 FTP**
- 2.4 Electronic Mail
 SMTP, POP3, IMAP
 2.5 DNS

- **2.6** P2P applications
- 2.7 Socket programming with TCP
- 2.8 Socket programming with UDP
- 2.9 Building a Web server

DNS: Domain Name System

People: many identifiers:

SSN, name, passport #

Internet hosts, routers:

- IP address (32 bit) used for addressing datagrams
- "name", e.g.,
 ww.yahoo.com used by
 humans
- Q: map between IP addresses and name ?

Domain Name System:

- distributed database implemented in hierarchy of many name servers
- application-layer protocol host, routers, name servers to communicate to resolve names (address/name translation)
 - note: core Internet function, implemented as application-layer protocol
 - complexity at network's "edge"

<u>DNS</u>

DNS services

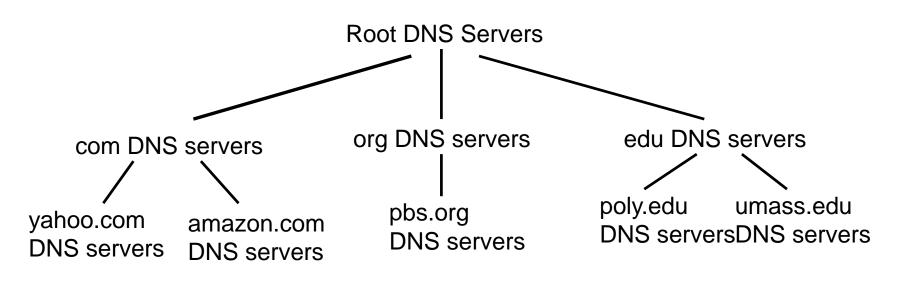

- hostname to IP address translation
- host aliasing
 - Canonical, alias names
- mail server aliasing
- load distribution
 - replicated Web servers: set of IP addresses for one canonical name

Why not centralize DNS?

- □ single point of failure
- traffic volume
- distant centralized database
- maintenance

doesn't scale!

Distributed, Hierarchical Database

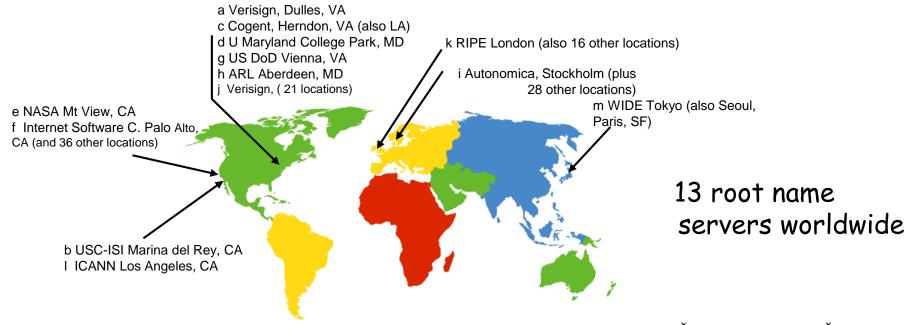

<u>Client wants IP for www.amazon.com; 1st approx:</u>

- client queries a root server to find com DNS server
- client queries com DNS server to get amazon.com DNS server
- client queries amazon.com DNS server to get IP address for www.amazon.com

DNS: Root name servers

- contacted by local name server that can not resolve name
- root name server:
 - contacts authoritative name server if name mapping not known
 - gets mapping
 - returns mapping to local name server

TLD and Authoritative Servers

Top-level domain (TLD) servers:

- responsible for com, org, net, edu, etc, and all top-level country domains uk, fr, ca, jp.
- Network Solutions maintains servers for com TLD
- Educause for edu TLD

Authoritative DNS servers:

- organization's DNS servers, providing authoritative hostname to IP mappings for organization's servers (e.g., Web, mail).
- can be maintained by organization or service provider

does not strictly belong to hierarchy

- each ISP (residential ISP, company, university) has one.
 - * also called "default name server"
- when host makes DNS query, query is sent to its local DNS server

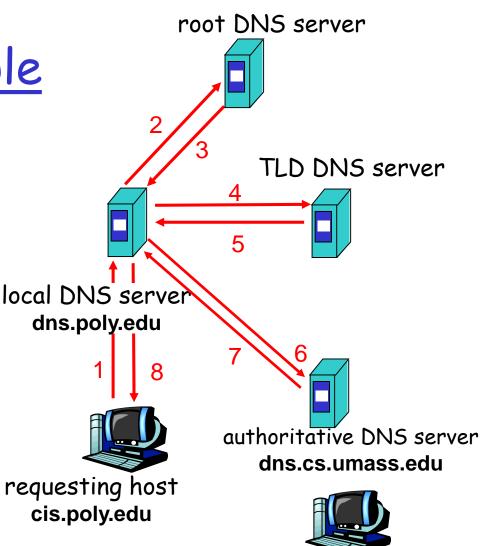

* acts as proxy, forwards query into hierarchy

<u>DNS name</u> resolution example

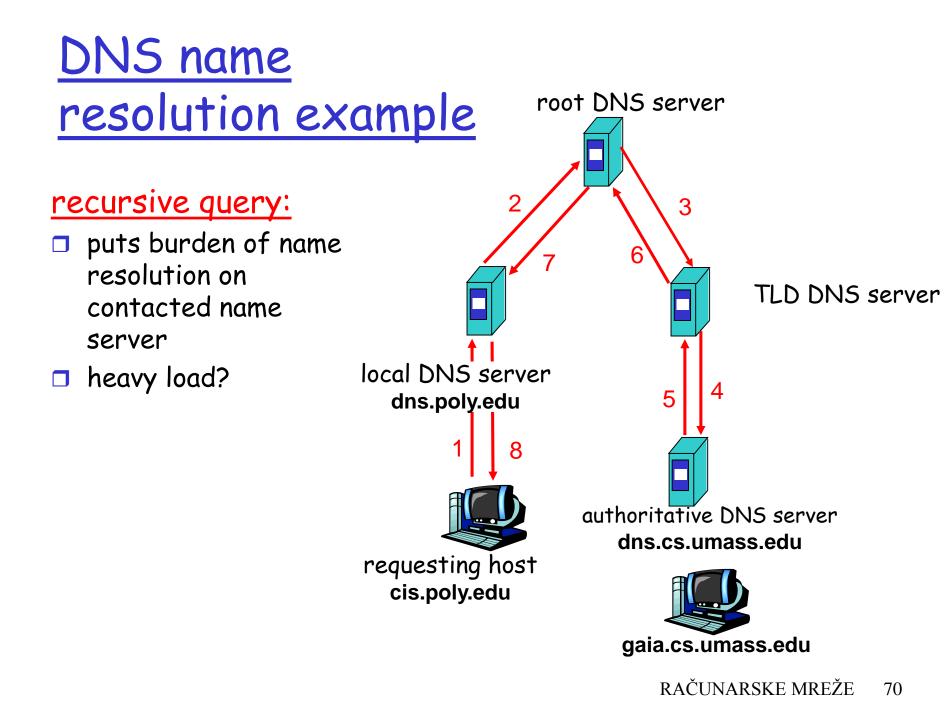

Host at cis.poly.edu wants IP address for gaia.cs.umass.edu

iterated query:

- contacted server replies with name of server to contact
- "I don't know this name, but ask this server"

gaia.cs.umass.edu

DNS: caching and updating records

- once (any) name server learns mapping, it caches mapping
 - cache entries timeout (disappear) after some time
 - TLD servers typically cached in local name servers
 - Thus root name servers not often visited
- update/notify mechanisms under design by IETF * RFC 2136
 - http://www.ietf.org/html.charters/dnsind-charter.html

DNS records

DNS: distributed db storing resource records (RR)

RR format: (name, value, type, ttl)

- Type=A
 - name is hostname
 - value is IP address
- Type=NS
 - name is domain (e.g. foo.com)
 - value is hostname of authoritative name server for this domain

□ Type=CNAME

- value is canonical name
- Type=MX
 - value is name of mailserver associated with name

DNS protocol, messages

<u>DNS protocol</u>: *query* and *reply* messages, both with same *message format*

msg header

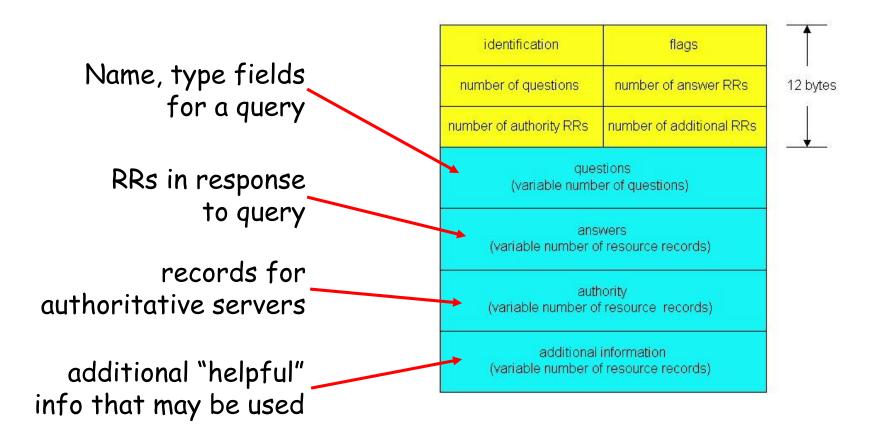

identification: 16 bit # for query, reply to query uses same #

□ flags:

- query or reply
- recursion desired
- recursion available
- reply is authoritative

identification	flags	Ī
number of questions	number of answer RRs	12 bytes
number of authority RRs	number of additional RRs	
questions (variable number of questions)		
answers (variable number of resource records)		
	iority Fresource records)	
additional (variable number o	information f resource records)	

DNS protocol, messages

Inserting records into DNS

example: new startup "Network Utopia"

- register name networkuptopia.com at DNS registrar (e.g., Network Solutions)
 - provide names, IP addresses of authoritative name server (primary and secondary)
 - registrar inserts two RRs into com TLD server:

(networkutopia.com, dns1.networkutopia.com, NS)
(dns1.networkutopia.com, 212.212.212.1, A)

- create authoritative server Type A record for www.networkuptopia.com; Type MX record for networkutopia.com
- How do people get IP address of your Web site?

Chapter 2: Application layer

- 2.1 Principles of network applications
 * app architectures
 * app requirements
 2.2 Web and HTTP
- 2.4 Electronic Mail
 SMTP, POP3, IMAP
- **2.5 DNS**

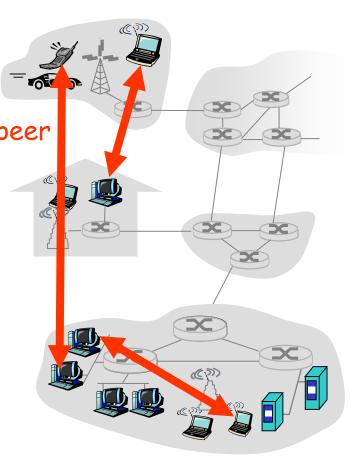

- 2.6 P2P applications
- 2.7 Socket programming with TCP
- 2.8 Socket programming with UDP

<u>Pure P2P architecture</u>

- □ *no* always-on server
- arbitrary end systems directly communicate
- peers are intermittently connected and change IP addresses

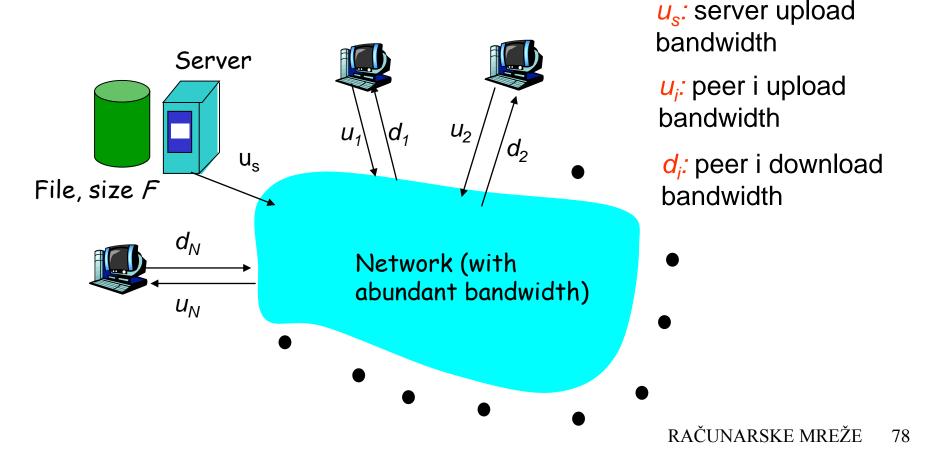

Three topics:

- File distribution
- Searching for information
- Case Study: Skype

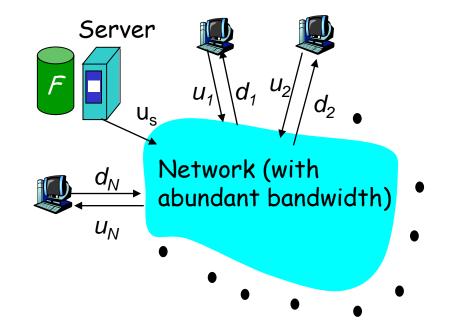

File Distribution: Server-Client vs P2P

<u>Question</u>: How much time to distribute file from one server to N peers?

File distribution time: server-client

server sequentially sends N copies:
 NF/u_s time
 client i takes F/d_i time to download

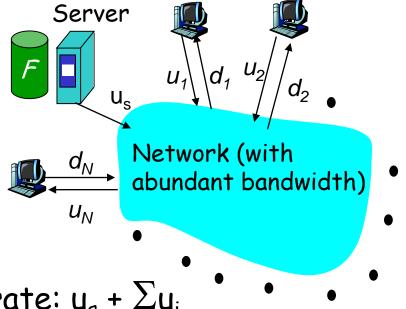

Time to distribute Fto N clients using = $d_{cs} = max \{ NF/u_{s}, F/min(d_i) \}$ client/server approach increases linearly in N (for large N)_{RAČUNARSKE MREŽE} 79

File distribution time: P2P

- server must send one copy: F/u_s time
- client i takes F/d_i time to download
- NF bits must be downloaded (aggregate)

 \Box fastest possible upload rate: $u_s + \Sigma u_i$

$$d_{P2P} = \max \{ F/u_s, F/min(d_i), NF/(u_s + \Sigma u_i) \}$$

<u>Server-client vs. P2P: example</u>

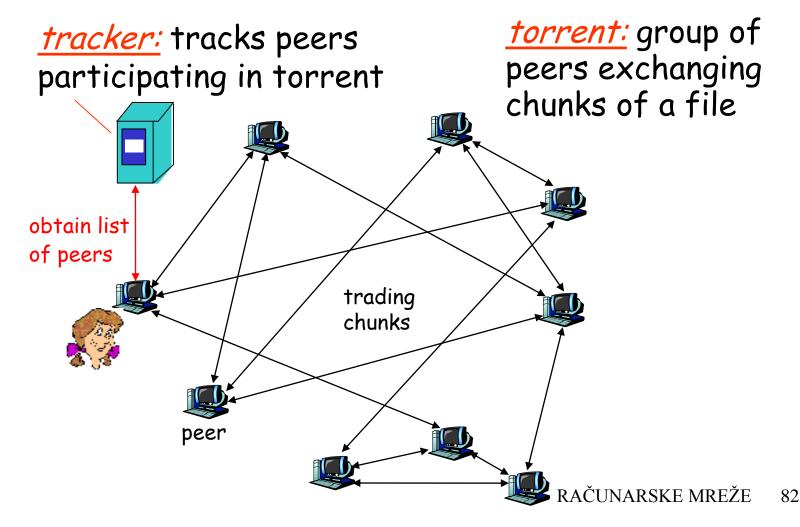

Client upload rate = u, F/u = 1 hour, $u_s = 10u$, $d_{min} \ge u_s$

RAČUNARSKE MREŽE 81

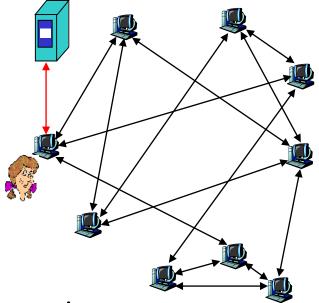

File distribution: BitTorrent

P2P file distribution

BitTorrent (1)

- file divided into 256KB chunks.
- peer joining torrent:
 - * has no chunks, but will accumulate them over time
 - registers with tracker to get list of peers, connects to subset of peers ("neighbors")
- while downloading, peer uploads chunks to other peers.
- peers may come and go
- once peer has entire file, it may (selfishly) leave or (altruistically) remain

<u>BitTorrent (2)</u>

Pulling Chunks

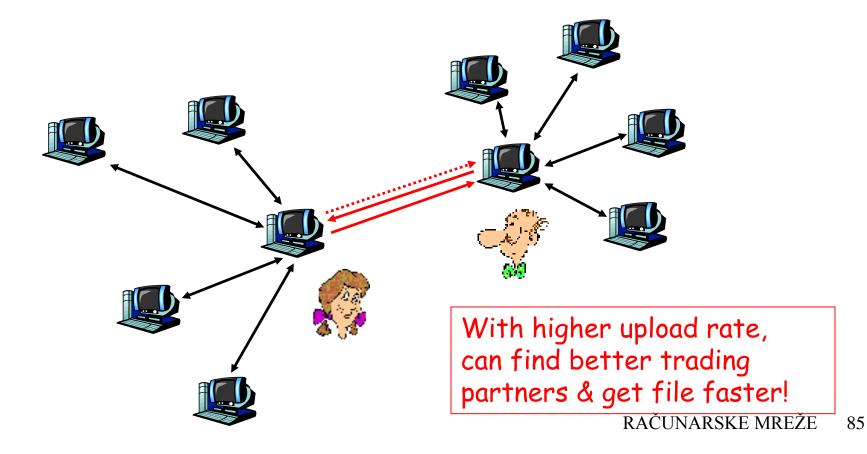

- at any given time, different peers have different subsets of file chunks
- periodically, a peer
 (Alice) asks each
 neighbor for list of
 chunks that they have.
- Alice sends requests for her missing chunks
 * rarest first

<u>Sending Chunks: tit-for-tat</u>

- Alice sends chunks to four neighbors currently sending her chunks at the highest rate
 - re-evaluate top 4 every
 10 secs
- every 30 secs: randomly select another peer, starts sending chunks
 - newly chosen peer may join top 4
 - * "optimistically unchoke"

BitTorrent: Tit-for-tat

(1) Alice "optimistically unchokes" Bob
(2) Alice becomes one of Bob's top-four providers; Bob reciprocates
(3) Bob becomes one of Alice's top-four providers

P2P: searching for information

Index in P2P system: maps information to peer location (location = IP address & port number)

File sharing (eg e-mule)

- Index dynamically tracks the locations of files that peers share.
- Peers need to tell index what they have.
- Peers search index to determine where files can be found

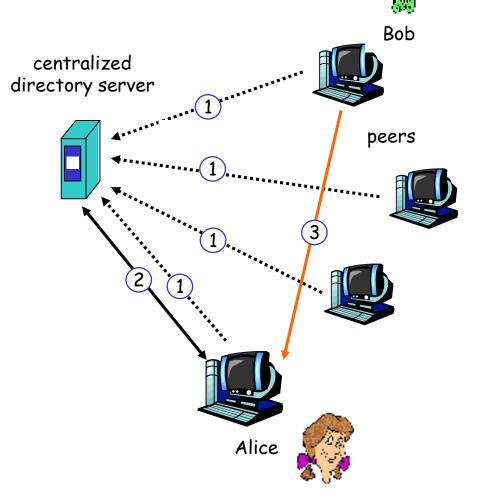

Instant messaging

- Index maps user names to locations.
- When user starts IM application, it needs to inform index of its location
- Peers search index to determine IP address of user.

P2P: centralized index

original "Napster" design

- 1) when peer connects, it informs central server:
 - IP address
 - content
- 2) Alice queries for "Hey Jude"
- 3) Alice requests file from Bob

P2P: problems with centralized directory

- □ single point of failure
- performance bottleneck
- copyright infringement:
 "target" of lawsuit is obvious

file transfer is decentralized, but locating content is highly centralized

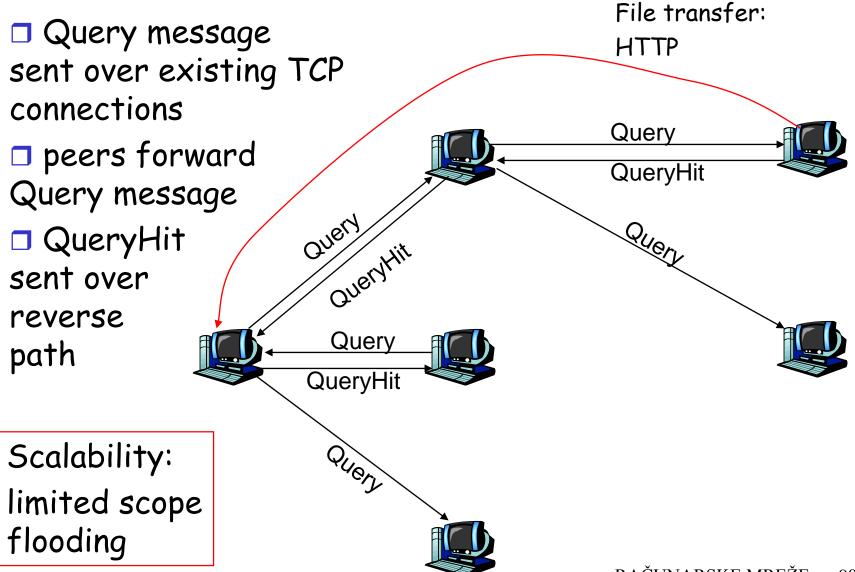

Query flooding

- fully distributed
 - no central server
- used by Gnutella
- Each peer indexes the files it makes available for sharing (and no other files)

overlay network: graph

- edge between peer X and Y if there's a TCP connection
- all active peers and edges form overlay net
- edge: virtual (not physical) link
- given peer typically connected with < 10 overlay neighbors

Query flooding

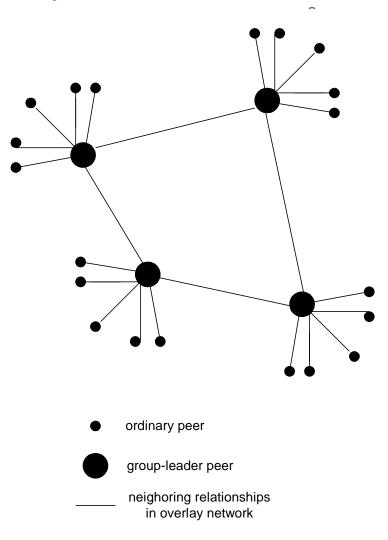

Gnutella: Peer joining

- joining peer Alice must find another peer in Gnutella network: use list of candidate peers
- 2. Alice sequentially attempts TCP connections with candidate peers until connection setup with Bob
- *3. Flooding:* Alice sends Ping message to Bob; Bob forwards Ping message to his overlay neighbors (who then forward to their neighbors....)
 - peers receiving Ping message respond to Alice with Pong message
- 4. Alice receives many Pong messages, and can then setup additional TCP connections

Peer leaving: see homework problem!

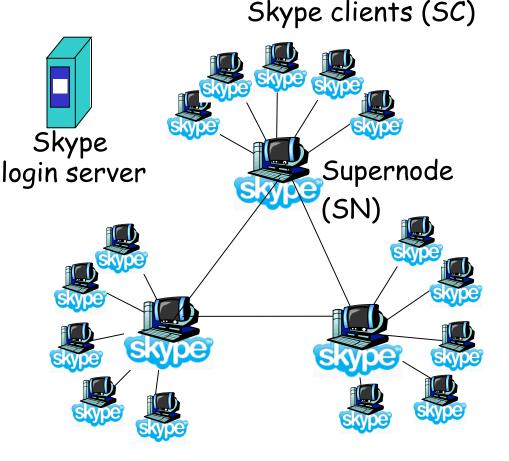

Hierarchical Overlay

- between centralized index, query flooding approaches
- each peer is either a super node or assigned to a super node
 - TCP connection between peer and its super node.
 - TCP connections between some pairs of super nodes.
- Super node tracks content in its children

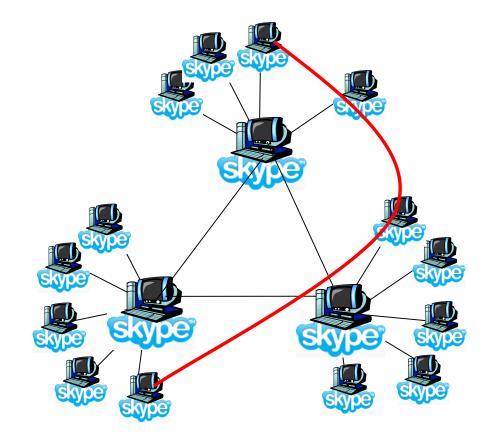

P2P Case study: Skype

- inherently P2P: pairs of users communicate.
- proprietary application-layer protocol (inferred via reverse engineering)
- hierarchical overlay with SNs
- Index maps usernames to IP addresses; distributed over SNs

Peers as relays

- Problem when both Alice and Bob are behind "NATs".
 - NAT prevents an outside peer from initiating a call to insider peer
- **Solution**:
 - Using Alice's and Bob's SNs, Relay is chosen
 - Each peer initiates session with relay.
 - Peers can now communicate through NATs via relay

Chapter 2: Application layer

- 2.1 Principles of network applications
- 2.2 Web and HTTP
- **2.3 FTP**
- 2.4 Electronic Mail
 SMTP, POP3, IMAP
- **2.5 DNS**

- 2.6 P2P applications
- 2.7 Socket programming with TCP
- 2.8 Socket programming with UDP

Socket programming

<u>Goal:</u> learn how to build client/server application that communicate using sockets

Socket API

- introduced in BSD4.1 UNIX, 1981
- explicitly created, used, released by apps
- client/server paradigm
- two types of transport service via socket API:
 - unreliable datagram
 - reliable, byte streamoriented

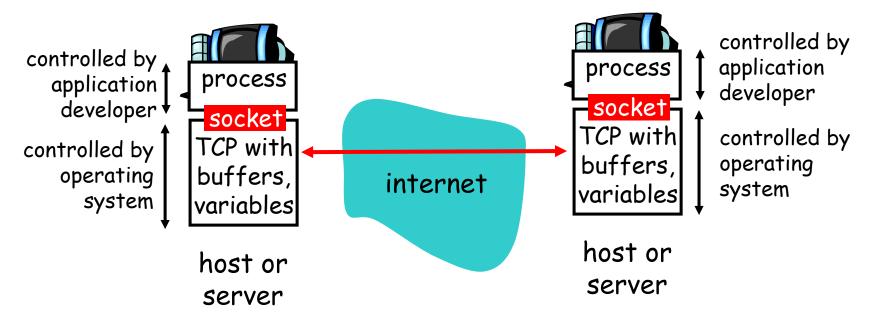

- socket -

a *host-local*, *application-created*, *OS-controlled* interface (a "door") into which application process can both send and receive messages to/from another application process

Socket-programming using TCP

<u>Socket:</u> a door between application process and endend-transport protocol (UCP or TCP) <u>TCP service:</u> reliable transfer of bytes from one

process to another

Socket programming with TCP

Client must contact server

- server process must first be running
- server must have created socket (door) that welcomes client's contact

Client contacts server by:

- creating client-local TCP socket
- specifying IP address, port number of server process
- When client creates socket: client TCP establishes connection to server TCP

- When contacted by client, server TCP creates new socket for server process to communicate with client
 - allows server to talk with multiple clients
 - source port numbers used to distinguish clients (more in Chap 3)

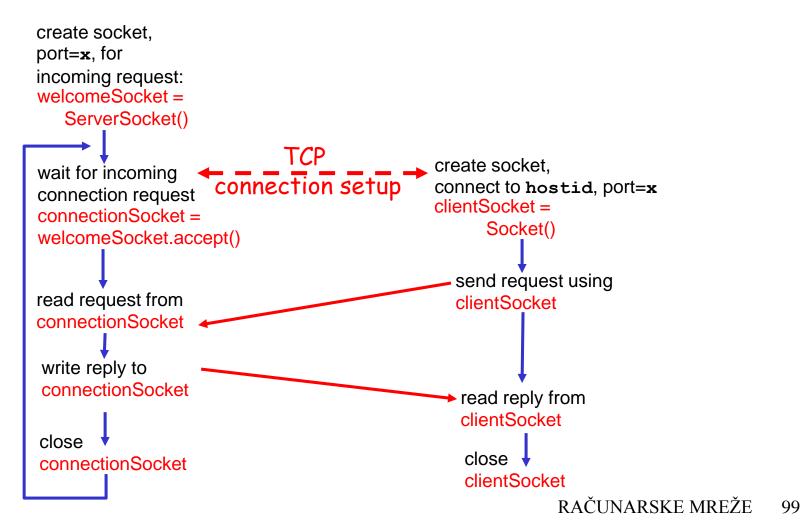

-application viewpoint-

TCP provides reliable, in-order transfer of bytes ("pipe") between client and server

Client/server socket interaction: TCP

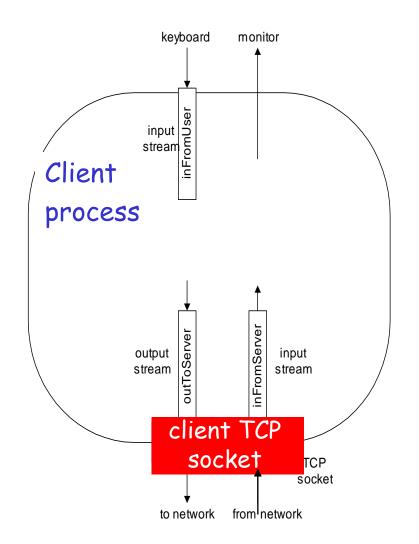

Server (running on hostid)

Client

Stream jargon

- A stream is a sequence of characters that flow into or out of a process.
- An input stream is attached to some input source for the process, e.g., keyboard or socket.
- An output stream is attached to an output source, e.g., monitor or socket.

Socket programming with TCP

Example client-server app:

- client reads line from standard input (inFromUser stream), sends to server via socket (outToServer stream)
- 2) server reads line from socket
- 3) server converts line to uppercase, sends back to client
- 4) client reads, prints modified line from socket (inFromServer stream)

Example: Java client (TCP)

Create⁻

output stream

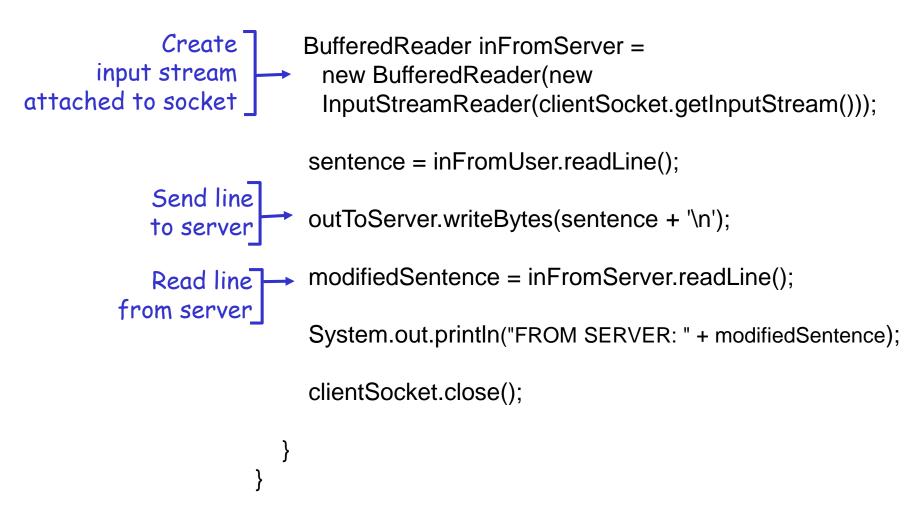

attached to socket

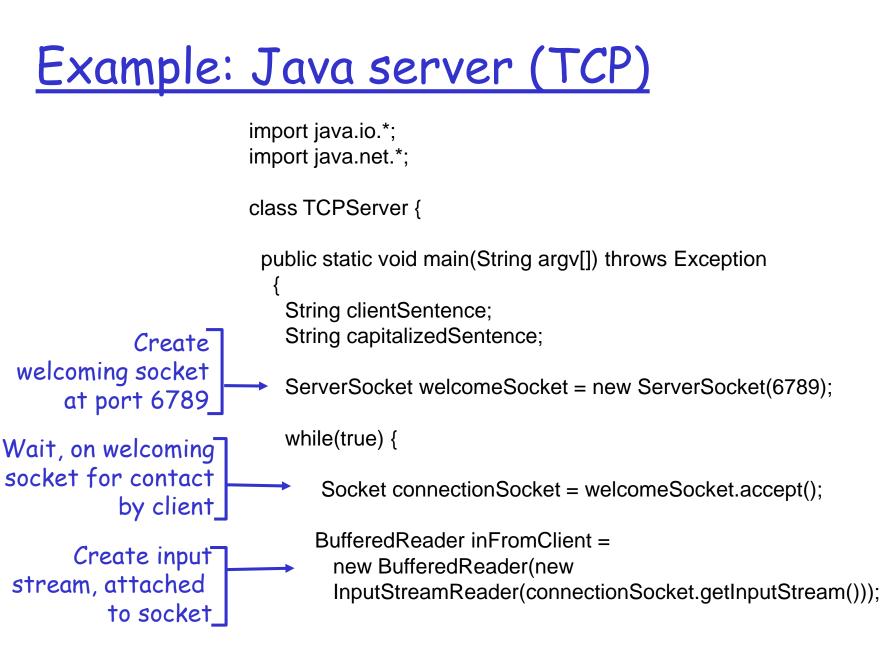

```
import java.io.*;
                    import java.net.*;
                    class TCPClient {
                      public static void main(String argv[]) throws Exception
                         String sentence;
                         String modifiedSentence;
           Create
                         BufferedReader inFromUser =
     input stream
                          new BufferedReader(new InputStreamReader(System.in));
          Create<sup>-</sup>
   client socket,
                         Socket clientSocket = new Socket("hostname", 6789);
connect to server
```

DataOutputStream outToServer =
 new DataOutputStream(clientSocket.getOutputStream());

Example: Java server (TCP), cont

Chapter 2: Application layer

- 2.1 Principles of network applications
- 2.2 Web and HTTP
- **2.3 FTP**
- 2.4 Electronic Mail
 SMTP, POP3, IMAP
 2.5 DNS

- □ 2.6 P2P applications
- 2.7 Socket programming with TCP
- 2.8 Socket programming with UDP

Socket programming with UDP

- UDP: no "connection" between client and server
- no handshaking
- sender explicitly attaches
 IP address and port of
 destination to each packet
- server must extract IP address, port of sender from received packet
- UDP: transmitted data may be received out of order, or lost

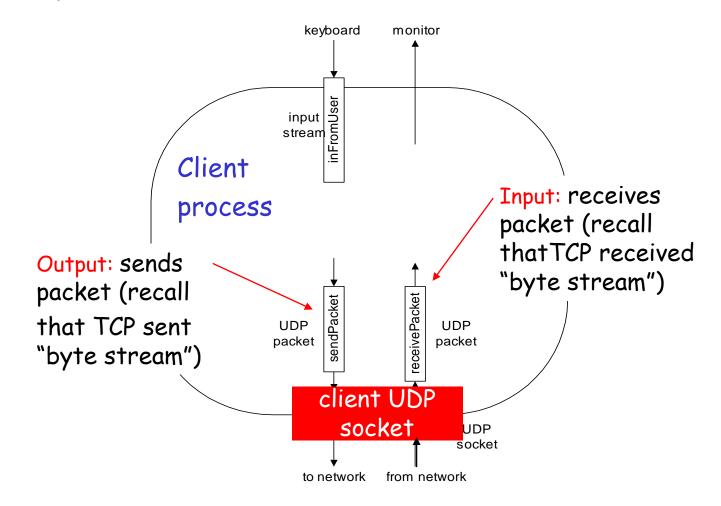

rapplication viewpoint.

UDP provides <u>unreliable</u> transfer of groups of bytes ("datagrams") between client and server

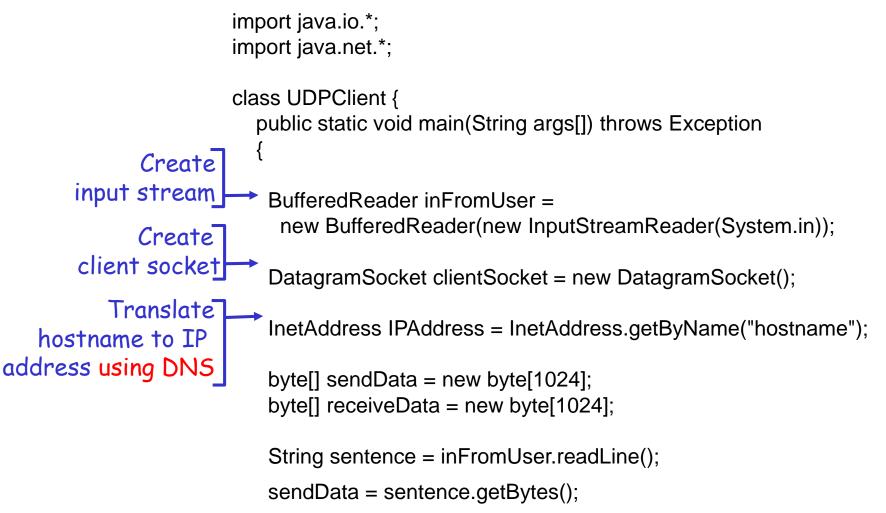

<u>Client/server socket interaction: UDP</u>

Client Server (running on hostid) create socket. create socket. clientSocket = port= x. DatagramSocket() serverSocket = DatagramSocket() Create datagram with server IP and port=x; send datagram via clientSocket read datagram from serverSocket write reply to serverSocket read datagram from specifying clientSocket client address. port number close clientSocket

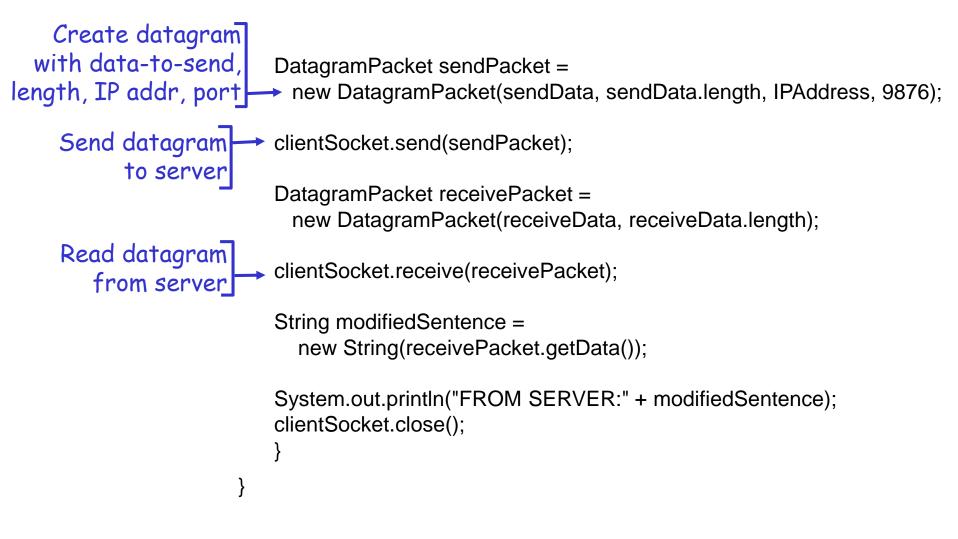

Example: Java client (UDP)

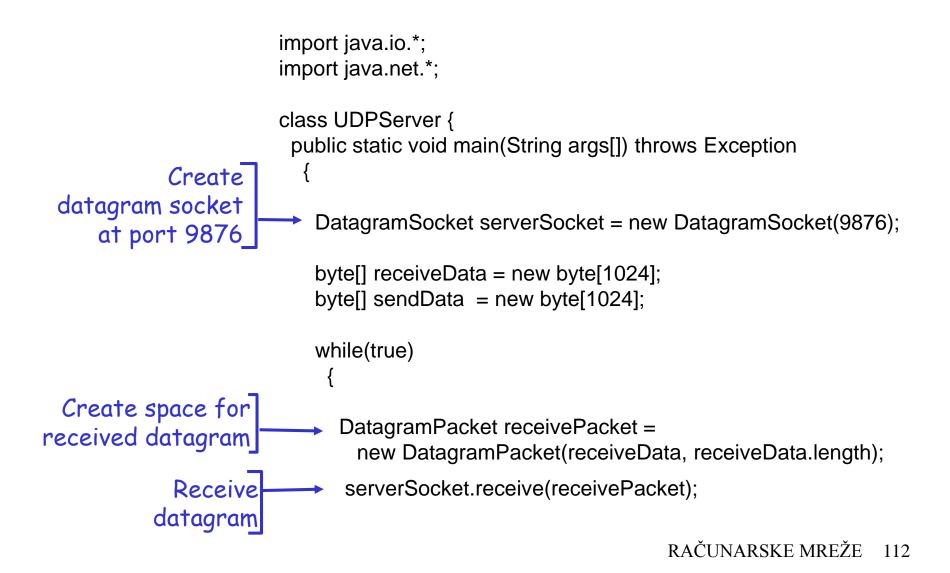

Example: Java client (UDP)

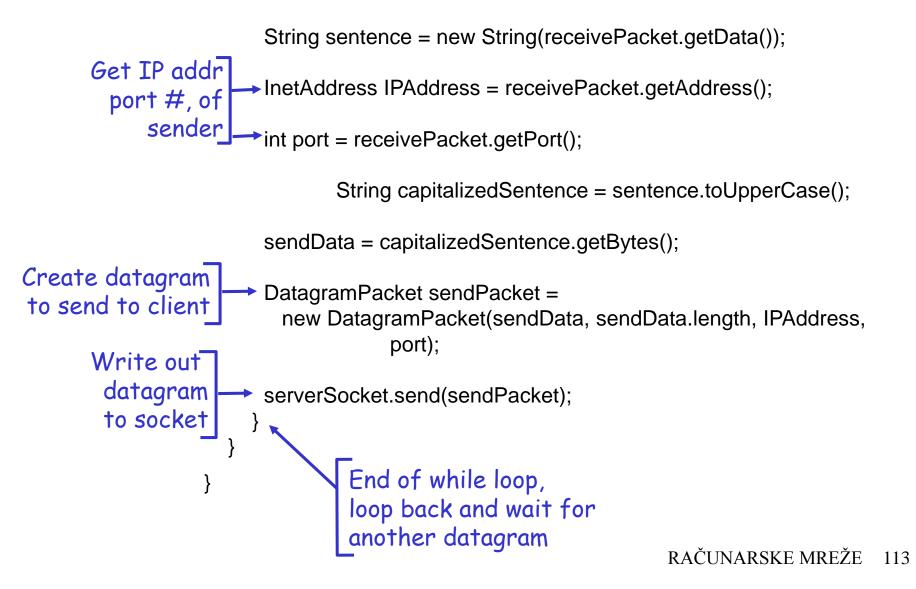

Example: Java client (UDP), cont.

Example: Java server (UDP)

Example: Java server (UDP), cont

Chapter 2: Summary

our study of network apps now complete!

- application architectures
 - client-server
 - P2P
 - hybrid
- application service requirements:
 - reliability, bandwidth, delay
- Internet transport service model
 - connection-oriented, reliable: TCP
 - unreliable, datagrams: UDP

specific protocols:

- * HTTP
- ✤ FTP
- ✤ SMTP, POP, IMAP
- DNS
- P2P: BitTorrent, Skype
- socket programming

Chapter 2: Summary

<u>Most importantly:</u> learned about *protocols*

- typical request/reply message exchange:
 - client requests info or service
 - server responds with data, status code
- message formats:
 - headers: fields giving info about data
 - data: info being communicated

Important themes:

- 🗖 control vs. data msgs
 - in-band, out-of-band
- centralized vs. decentralized
- 🗖 stateless vs. stateful
- reliable vs. unreliable msg transfer
- "complexity at network edge"
